Web-E-Vil

Inspired by the social experiment, r/place, Web-E-Vil offers a fun, and unique space to collaborate with a community by creating pixel art.

Tools Used 1

Docker manages the containers necessary to build our application.
5/5

Postgres Database

Using Postgres we stored: Login Info (Hashed Pwds, Email, Username), Persistent Pixel Info (Location, color, created_by)
5/5

Handlebars

Handlebars offered easy creation of our home, login, and registration pages using templates.
5/5

Git/Github/Github Projects

Version Control, and project management
5/5.

Render

Using render we were able to deploy the application over the cloud.
4/5

Tools Used 2

VS-Code

We used VScode to do the coding for the project. This allowed us to use extensions to optimize web development.
5/5

NodeJS

Using NodeJS we connected our db, server/client UI, and security middleware to create the app.
5/5

Mocha

Using Mocha we were able to develop unit tests for the application. **3/5**

Express

HTTP Response/ Request framework.
4/5.

Methodologies

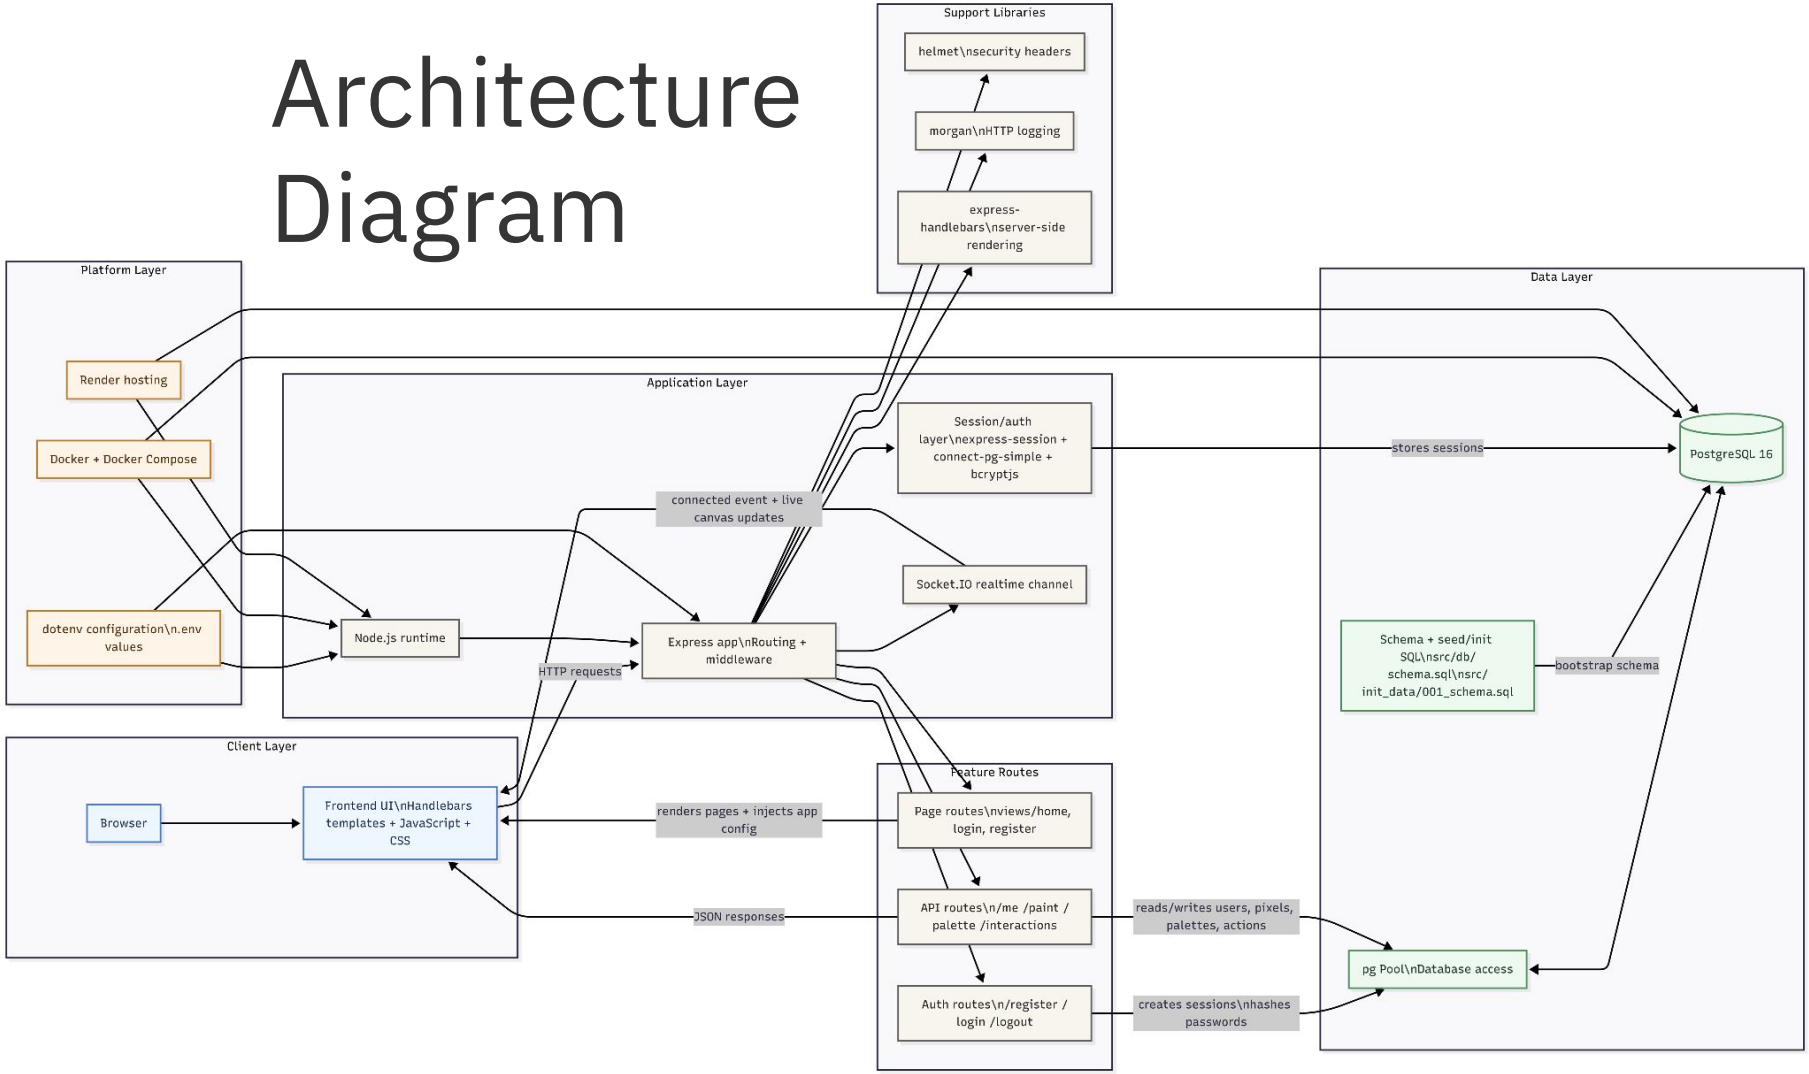
AGILE: We used an agile methodology by completing the application in parts.
SCRUM: Each week our scrum master decided which user storys/features to address.
4/5.

Meetings

Weekly meetings on Mondays via Discord.
During these meetings we usually prepared for our meeting with our TA by discussing current features and issues we ran into. This time also helped to resolve merge conflicts as we can work collaboritively to decide what to keep and what to change.

Weekly meetings on Wednesday with our TA.
During these meetings we usually would discuss the current scope of the project and any changes to that scope that we have considered.
Additionally we talked about current release features, and our plan for the coming week.

Architecture Diagram



Challenges

1

We found it difficult to meet consistently, with everything else going on in our other classes.

Solution:

Incremental progress, individual accountability, and individual meetings.

2

Effective communication, i.e project scope and goals, and individual responsibilities vs. team responsibilities.

Solution:

Project management via Github Projects, and learning from eachother on what is needed by the team.

3

Game Design and scope growth.

Solution:

Sprint based development helped to not get too bogged down on the game design details, and instead focused on a working product each week, with new features being added.

Impacts to Original Plans

1. We planned on meeting much more consistently in the beginning, so with less team work time, I think we collaborated a little less than we had planned, and instead worked much more individually, then merged our commits when the time came.
2. We expected to maintain a more organized task list, but with the changes in scope and features we wanted to add, a lot of the time it happened less formulaically.
3. We planned to add a lot more features, especially around social interaction, but this became complex to work concurrently on, so we had to wait until more progress was made on the base game, which left no time near the end of development to finish those features.

Future Enhancements

	Potential enhancement	Rough Idea of the Implementation
1	More social interaction	By adding a friends list, and then allowing users to see their friends creations, we could encourage more collaboration and interaction.
2	More oppurtunities for XP	Using daily events, interaction rewards (XP for receiving likes/giving likes) we could further encourage participation within the canvas.
3	Mobile Compatibility	Currently, the mobile UI does not work, which definitely limits the ease of access since many people play games on their phone.

Live Demo!

https://web-app-social-experiment.onrender.com/

This works best on computer.

Any questions?

Thank you
